EP 0 659 500 B1

Description

The present invention relates to a method of bending a pipe having an oblong cross-section for heat exchangers.

In heat exchangers of the mechanical expansion type (in which the stack of fins is secured to the pipes by a pipe expanding or mechanical expansion process), the use of pipes bent in a U-shape (so-called forked pipes) enables a collector plate and a tank for recirculating the refrigerating fluid to be dispensed with, evidently saving material and increasing the reliability of the heat exchanger since, with the same number of pipes, the fluidtight points present as a whole are reduced by half.

The use of forked pipes is common today for aluminium or copper pipes with a circular section, whilst, for pipes having a flat or oblong section, it is difficult and, in fact, impracticable, when the flat pipe has to be bent in a U-shape and the two limbs of the fork maintained aligned along the longer axis of their cross-section.

The object of the present invention is to provide a method of bending a pipe having an oblong cross-section in a U-shaped arrangement which permits the two limbs of the pipe to be placed in a position in which the longer axes of the respective cross-sections are aligned with or parallel to one another without causing excessive stretching of the material in the bending zone.

According to the present invention, this object is achieved by a method comprising the following steps:

- causing a relative rotation substantially equal to 180° between two limbs of the pipe about an axis parallel to the longer axis of the cross-section of the pipe, so as to obtain two straight limbs with longer axes of the respective cross-sections parallel to one another and connected to one another by a curved connecting portion; and
- causing a relative rotation between each of the straight limbs and the connecting portion about an axis coinciding with or parallel to the longitudinal axis of the straight limbs.

The present invention also relates to a method of manufacturing a heat exchanger comprising a stack of fins fixed to a plurality of pipes having an oblong cross-section, in which each pipe has two straight limbs and a curved connecting portion, the longer axes of the respective cross-sections of the two straight limbs of each pipe being aligned with or parallel to one another, and the connecting portion having an oblong cross-section with a longer axis at a right-angle to the longer axes of the cross-sections of the straight limbs, characterised in that the pipes are bent by the method according to the invention.

Further preferred characteristics and advantages of the present invention will become clear from the following detailed description given purely by way of example, with reference to the appended drawings, in which:

- Figure 1 is a schematic perspective view of a heat exchanger manufactured by the method according to the present invention;

5 - Figures 2, 3 and 4 illustrate schematically the bending stages of a pipe;

- Figure 5 is a view of the connecting portion of a pipe along the arrow V of Figure 1; and

10 - Figure 6 is a view of the pipe bent along the arrow VI of Figure 5.

Referring firstly to Figures 2, 3 and 4, a method is described for bending a pipe having an oblong cross-section into a U-shape. In the example illustrated in the drawings, reference is made to a pipe with a flat section, however, it will be understood that the process according to the invention can generally be adapted to pipes with an oblong section, this term covering oval, ovoid, etc. sections and in general sections in which it is possible to differentiate between a longer axis and a shorter axis of different lengths.

15 In the drawings, the pipe is indicated by the reference numeral 2 whilst the longer axis of the cross-section of the pipe is indicated 4.

With reference to Figure 2, a reinforcing core 6 consisting of a flexible element of a shape such that it freely and slidably engages the hole in the pipe is inserted in the initially straight pipe 2. The reinforcing core 6 is inserted over a length such that it extends over at least the entire pipe-bending zone. When the core has been inserted, a relative rotation substantially equal to 180° of two limbs 2a, 2b of the pipe 2 is caused about a bending axis 8 parallel to the axis 4 of the cross-section of the pipe (Figure 3).

25 The pipe 2 is bent by a known tool comprising a wheel having a radius equal to the radius of curvature of the pipe and a movable shaping member which urges the pipe against the edge of the wheel, creating the curved connecting portion 2c between the two straight limbs 2a, 2b.

30 When the pipe has been bent into the U-shape, the two straight limbs 2a, 2b are located with the longer axes 4 of the respective cross-sections parallel to one another. After this first bending of the pipe 2, the reinforcing core 6 is partially removed such that the reinforcing core only extends over one of the two limbs of the pipe and that the end of the core is located approximately in correspondence with the part in which the straight limb starts to curve. A second core 6' (Figure 4) which is introduced into the limb approximately as far as the point at which the limb joins the curved connecting portion 2c is disposed in the limb which does not have the reinforcing core.

35 At this point, a relative rotation of 90° of each of the two limbs 2a, 2b relative to the curved connecting portion 2c is caused about an axis which coincides with or, 40

generally, is parallel to the longitudinal axis of the straight limbs 2a, 2b. This relative rotation is performed by immobilising the connecting portion 2c and holding the straight limbs 2a, 2b from the exterior with gripper members which impart the necessary rotation. At the end of this operation, the pipe assumes the shape shown in Figure 4, with the longer axes 4 of the straight limbs 2a, 2b aligned relative to one another or, in general, parallel to one another. The reinforcing cores 6, 6' are then withdrawn and a plurality of fins which are secured to the pipes by expansion of the pipes, according to a known technology, are then fitted on the straight limbs 2a, 2b of a series of parallel pipes.

During the pipe-bending process, the object of the flexible reinforcing core is to prevent the pipe from yielding. The same result can be obtained by introducing a material which melts at a temperature far lower than the melting temperature of the material forming the pipe into the pipe. This material is introduced into the pipe in the liquid state and is solidified before the bending process is performed. At the end of the bending operations, this material is removed again in the liquid state by heating the pipe.

Figure 1 shows schematically a heat exchanger with pipes having an oblong section and bent according to the process described above. The flow of air strikes the heat exchanger in the direction indicated by the arrows A in Figure 1 and the pipes are located with their longer axis parallel to the direction of the air flow in a manner similar to that which occurs in heat exchangers having two collector tanks situated at the opposite ends of the stack of sheets. The fact that the longer axes 4 of the pipes are aligned with or parallel to one another enables a liquid inlet zone and a return zone to be provided in the collector tank by means of a simple longitudinal separating plate schematically indicated 10 in Figure 6.

Claims

1. A method of bending a pipe having an oblong cross-section for heat exchangers, comprising the steps of:

- causing a relative rotation substantially equal to 180° between two limbs (2a, 2b) of the pipe (2) about an axis (8) parallel to the longer axis (4) of the cross-section of the pipe, so as to obtain two straight limbs with longer axes (4) of the respective cross-sections parallel to one another and connected to one another by a curved connecting portion (2c); and
- causing a relative rotation between each of the above straight limbs (2a, 2b) and the connecting portion (2c) about an axis coinciding with or parallel to the longitudinal axis of the straight limbs.

2. A method according to Claim 1, characterised in that the relative rotation between each of the straight limbs (2a, 2b) and the connecting portion is substantially equal to 90°.

3. A method according to Claim 1, characterised in that the pipe (2) is bent by inserting a reinforcing core (6, 6') in the pipe (2) beforehand.

4. A method according to Claim 3, characterised in that the reinforcing core is a flexible element (6, 6') which can slide freely in the pipe (2).

5. A method according to Claim 3, characterized in that the reinforcing core (6, 6') is produced by a material which melts at a temperature which is substantially lower than the melting temperature of the material constituting the pipes, the material being introduced into the pipe (2) in the liquid state and being made to solidify before the bending method is performed, the molten material then being removed from the pipe (2) in the liquid state by heating the pipe (2).

6. Method of manufacturing a heat exchanger comprising a stack of fins secured to a plurality of pipes (2) having an oblong cross-section, in which each pipe (2) has two straight limbs (2a, 2b) and a curved connecting portion (2c), the longer axes of the respective cross-sections of the two straight limbs (2a, 2b) of each pipe (2) being aligned with or parallel to one another, and the connecting portion (2c) having an oblong cross-section with a longer axis at a right-angle to the longer axes of the cross-sections of the straight limbs (2a, 2b) characterised in that the pipes are bent by the method according to claims 1 to 5.

Patentansprüche

1. Verfahren zum Biegen eines Rohres mit länglichem Querschnitt für Wärmetauscher, das die Schritte:

- verursachen einer relativen Drehung um im wesentlichen 180° zwischen zwei Gliedern (2a, 2b) des Rohres (2) um eine Achse (8) parallel zu der längeren Achse (4) des Querschnittes des Rohres, um zwei gerade Glieder mit längeren Achsen (4) der jeweiligen Querschnitte zu erhalten, die parallel zueinander und miteinander durch einen gekrümmten Verbindungsteil (2c) verbunden sind; und
- verursachen einer relativen Drehung zwischen jedem der oben genannten, geraden Glieder (2a, 2b) und dem Verbindungsteil (2c) um eine Achse, die mit der Längsachse der geraden Glieder zusammenfällt oder zu ihr parallel ist; umfaßt.

2. Verfahren nach Anspruch 1, dadurch gekennzeichnet, daß die relative Drehung zwischen jedem der geraden Glieder (2a, 2b) und dem Verbindungsteil im wesentlichen 90° beträgt. 5
3. Verfahren nach Anspruch 1, dadurch gekennzeichnet, daß das Rohr (2) durch einen im voraus in das Rohr (2) eingesetzten, verstärkenden Kern (6, 6') gebogen ist. 10
4. Verfahren nach Anspruch 3, dadurch gekennzeichnet, daß der verstärkende Kern ein flexibles Element (6, 6') ist, das in dem Rohr (2) frei rutschen kann. 15
5. Verfahren nach Anspruch 3, dadurch gekennzeichnet, daß der verstärkende Kern (6, 6') aus einem Material hergestellt ist, das bei einer Temperatur schmilzt, die im wesentlichen geringer als die Schmelztemperatur des Materials ist, aus dem die Rohre aufgebaut sind und daß das Material in flüssigem Zustand in das Rohr (2) eingebracht wird und zum Erstarren gebracht wird bevor das Biegeverfahren durchgeführt wird, wobei das geschmolzene Material in flüssigem Zustand durch Aufheizen des Rohres (2) aus dem Rohr (2) entfernt wird. 20 25
6. Verfahren zur Herstellung eines Wärmetauschers, der einen Satz Rippen, die an einer Mehrzahl von einem länglichen Querschnitt aufweisenden Rohren (2) befestigt sind, wobei jedes Rohr (2) zwei gerade Glieder (2a, 2b) aufweist und einen gekrümmten Verbindungsteil (2c) hat, die längeren Achsen der jeweiligen Querschnitte der zwei geraden Glieder (2a, 2b) jedes Rohres (2) in einer geraden Linie oder parallel zueinander ausgerichtet sind und der Verbindungsteil (2c) einen länglichen Querschnitt hat mit einer längeren Achse in einem rechten Winkel zu der längeren Achse der Querschnitte der geraden Glieder (2a, 2b), dadurch gekennzeichnet, daß die Rohre nach einem Verfahren gemäß Anspruch 1 bis 5 gebogen sind. 30 35 40

Revendications 45

1. Procédé de cintrage d'un tube de section transversale oblongue, destiné à des échangeurs de chaleur, comprenant les étapes suivantes : 50
 - provoquer la rotation relative pratiquement égale à 180° entre deux branches (2a, 2b) du tube (2) autour d'un axe (8) parallèle au grand axe (4) de la section transversale du tube, afin que deux branches rectilignes ayant des grands axes (4) dont les sections transversales respectives sont parallèles et qui sont raccordées l'une à l'autre par une partie courbe (2c) 55

de raccordement soient obtenues, et
- provoquer la rotation relative entre chacune des branches rectilignes (2a, 2b) et de la partie de raccordement (2c) autour d'un axe qui coïncide avec l'axe longitudinal des branches rectilignes ou est parallèle à cet axe.

2. Procédé selon la revendication 1, caractérisé en ce que la rotation relative entre chacune des branches rectilignes (2a, 2b) et la partie de raccordement est pratiquement égale à 90°. 10
3. Procédé selon la revendication 1, caractérisé en ce que le tube (2) est cintré par insertion d'une âme d'armature (6, 6') dans le tube (2) au préalable. 15
4. Procédé selon la revendication 3, caractérisé en ce que l'âme d'armature est un élément flexible (6, 6') qui peut glisser librement dans le tube (2). 20
5. Procédé selon la revendication 3, caractérisé en ce que l'âme d'armature (6, 6') est produite en un matériau qui fond à une température nettement inférieure à la température de fusion du matériau constituant les tubes, le matériau étant introduit dans le tube (2) à l'état liquide et étant ensuite solidifié avant la mise en oeuvre du procédé de cintrage, le matériau moulé étant alors retiré du tube (2) à l'état liquide par chauffage du tube (2). 25
6. Procédé de fabrication d'un échangeur de chaleur comportant un empilement d'ailettes fixé à plusieurs tubes (2) ayant une section transversale oblongue, chaque tube (2) ayant deux branches rectilignes (2a, 2b) et une partie courbe de raccordement (2c), les grands axes des sections transversales respectives des deux branches rectilignes (2a, 2b) de chaque tube (2) étant alignés l'un sur l'autre ou parallèles l'un à l'autre, et la partie de raccordement (2c) ayant une section transversale oblongue avec un grand axe perpendiculaire aux grands axes des sections transversales des branches rectilignes (2a, 2b), caractérisé en ce que les tubes sont cintrés par mise en oeuvre du procédé selon les revendications 1 à 5. 30 35 40 45
